How do I Keep my electrical enclosure at the right temperature?

To keep your electrical enclosure at the right temperature, you'll need a cooling method that fits your setup. Some systems use natural airflow, while others rely on powered devices to manage heat. Let's break it down. Passive cooling doesn't use power--it works by helping heat escape naturally.

What temperature should a power enclosure be?

A good rule of thumb for many enclosures is to keep the internal temperature below 95°F (35°C). It's a safe middle ground--cool enough for most equipment to run reliably, but not so cold that you're overpaying for cooling. Temperature inside the enclosure isn't always even. Areas near VFDs, transformers, or power supplies tend to run hotter.

How do you manage enclosure temperature?

Understand Heat Load: Internal (devices) and external (sunlight, ambient temp) heat sources must both be accounted for when managing enclosure temperatures. Target Temperature: Keep internal temperatures below 95°F (35°C) to ensure safe and efficient operation. Passive: Vents, shade, and natural airflow - best for mild conditions.

What temperature should a sensor enclosure be cooled to?

Some devices, like sensitive sensors or electronics, may even require cooler conditions than others. A good rule of thumb for many enclosures is to keep the internal temperature below 95°F (35°C). It's a safe middle ground--cool enough for most equipment to run reliably, but not so cold that you're overpaying for cooling.
